# **Emulation Framework**

**Release 2.0.0 (February 2012)**

<b>Release date</b>	28 February 2012
<b>Release version</b>	2.0.0
<b>Author(s)</b>	Bram Lohman (Tessella) David Michel (Tessella) Edo Noordermeer (Tessella)
<b>Organisation</b>	KEEP project

## Executive Summary

This is the System Maintenance Guide (SMG) for the Emulation Framework. The EF is software developed by the international KEEP project, co-funded by the European Unions 7<sup>th</sup> Framework Programme.

The System Maintenance Guide outlines how to build and maintain the system, and how to set up the development environment.

Developed in Java, the system is by definition cross-platform and can therefore be developed on any platform that supports Java. Ant build scripts are provided to perform all necessary build tasks related to the project, such as compiling the source code, launching the unit test suite, setting up the database, running static analysis tools or building a release package.

The Emulation Framework has been developed as a library and can easily be integrated in external systems. However, it can also be run as a standalone tool; three access methods have been developed for this purpose: a built-in shell that allows direct access to the public Application Programming Interface (API), a basic Graphical User Interface (GUI) offering the most common functionalities for setting up an emulation environment for digital files, and a comprehensive GUI which offers more advanced functionalities. A list and description of the available commands for the shell is included in this document.

The Emulation Framework has three main external dependencies: an Emulator Archive, a Software Archive and a technical metadata registry. The Emulator Archive is used to access (certified) Emulator Packages. The Software Archive provides software images of operating systems and applications that the emulators require to render the environment. Finally, the technical metadata registry is required for retrieving information about which computer platform dependencies exist for digital objects (e.g. WordPerfect documents require the application WordPerfect, operating system MS DOS and an x86 PC or compatible architecture. For each of these dependencies, a simple prototype has been created to be able to fully demonstrate the Emulation Framework. The registry prototype is incorporated in the Software Archive prototype.

Several objects used within the framework, such as Emulator Packages, Software Packages, and Pathways make use of XML schemas describing their properties. For each of these objects, the relevant XML schema is described and a sample file is included.

Examples are provided showing how to employ the basic functionality of the framework when running from the Command Line Interface.

# 1 Introduction

## 1.1 Purpose and scope

This document provides information about how the Emulation Framework (EF) is constructed, maintained and deployed. It is intended for developers and, to a limited extent, system administrators who need to maintain the software. It does not describe how to use or install the system; this is covered by the EF System User Guide [SUG].

This document covers the core software, internal database and supporting objects that make up the Emulation Framework application. The aim of this document is to aid in developing, installing and maintaining the application.

Although this document gives an outline of the inner workings of the application, as well as the interfaces to external systems, it does not cover details of their setup or maintenance. Neither is this a detailed guide to the overall structure of the EF – this can be found in the EF Architectural Design Document [ADD].

## 1.2 Context of this Issue

This version of the SMG describes **version 2.0.0 of the Emulation Framework**.

This document describes the Emulation Framework environment that has been released in February 2012. This includes two prototype archives (Emulator and Software Archive), some sample test data, the Emulation Framework, and two GUIs.

## 1.3 About the KEEP project

KEEP (Keeping Emulation Environments Portable) is a research project co-funded by the European Union 7th Framework Programme. It does research into an emulation-based preservation strategy and develops several tools to support that. The consortium consists of nine organisations representing a wide range of stakeholders in Europe: cultural heritage institutes, research institutes, commercial partners and the gaming industry. The project has a duration of three years and ends February 2012.

More information can be found on the KEEP website: <http://www.keep-project.eu>

## 1.4 About the software in this release

The EF software is divided into **Core**, **comprehensive GUI**, **basic GUI**, **Software Archive** and **Emulator Archive** components.

The **Core** is the technical heart of the system, performing the automatic identification of file formats, selecting the required software and automatically configuring the emulation environment. The Core includes the **comprehensive GUI** to interact directly with the user, offering advanced functionalities including options to manage the Software Archive and Emulator Archive.

For selecting the software and emulator, the Core interacts with external services such as technical registries containing file format classifications, the **Software Archive** that contains disk images and the **Emulator Archive** that contains the emulators available for the EF.

The **basic GUI** has been developed as a separate component, and offers the most common functionalities for setting up an emulation environment for digital files.

The Core, Software Archive and Emulator Archive are developed by Tessella with support from the National Library of the Netherlands. The Comprehensive GUI is developed by the National Library of the Netherlands, with support from Tessella. The basic GUI is developed by the University of Portsmouth.

## 2 System Context and Interfaces

### 2.1 Overview and Context

The following diagram is taken from the URD. It shows the context and boundaries of the Emulation Framework. The task of the EF is to provide users access to digital objects of any kind via emulation.

**Figure 1 : EF system overview and system boundaries**

Figure 1 shows a high-level overview of the system (green, in scope) and its boundaries (grey, outside system scope). Within the EF a distinction is made in *Core* and *GUI*. The *Core* is responsible for managing emulation processes while the *GUI* (either comprehensive or basic) provides a rendering environment plus additional services to the user.

### 3 Configuration

The **Core**, **Emulator Archive** and **Software Archive** components can be configured using text-based property-files.

#### 3.1 Core configuration

The configuration of the Core is stored in a file called **user.properties**, located in the `./eu/keep` subdirectory, and contains the internal database connection properties, the location of the Emulator and Software Archive, as well as the various directories used by the system.

Property key	Default property value	Comment
h2.db.driver	org.h2.Driver	JDBC driver class
h2.jdbc.prefix	jdbc:h2:	JDBC url prefix
h2.db.url	./database/h2/EF_engine	Database location on disk
h2.db.exists	;IFEXISTS=TRUE	Flag to indicate whether the database should be created (FALSE), or fail (TRUE) if it doesn't exist.
h2.db.server	;AUTO_SERVER=TRUE	The database connection type
h2.db.schema	;SCHEMA=engine	Name of the schema used for the internal database
h2.db.admin	sa	Database admin login name
h2.db.adminpassw	CEF_Engine	Database admin password
h2.db.user	cef	Database user login name
h2.db.userpassw	cef	Database user password
software.archive.url	http://localhost:9000/softwarearchive/	Location of the Software Archive
emulator.archive.url	http://localhost:9001/emulatorarchive/	Location of the Emulator Archive
exec.dir	./exec	Temporary directory where the emulators are installed for use (will be deleted after use)
system.tmpdir	./tmp	Directory used by the host system to store temporary files
accepted.languages <sup>1</sup>	all	<p>Emulator and Software languages which are accepted. Emulators or Software which use other languages will not be selected or displayed.</p> <p>Languages are entered as a comma-separated list of 2-letter 'locale'-codes, e.g. en (English), nl (Dutch), fr (French), de (German). See appendix B for a complete list of language codes.</p> <p>To accept all available languages, enter 'all'.</p>

The comprehensive GUI has a separate configuration file called **gui.properties**, also located in the `./eu/keep` subdirectory.

This file contains the database connection parameters for the different	Default property value	Comment

<sup>1</sup> The list of accepted languages can also be configured via the EF GUI (see section 2.6 in the System User Guide).

swa.db.schema	;SCHEMA=softwarearchive	Name of the schema used for the internal database
swa.db.admin	sa	Database admin login name
swa.db.adminpassw	SWA_Engine	Database admin password
swa.db.user	swa	Database user login name
swa.db.userpassw	swa	Database user password
language	en	User language for the comprehensive GUI.  Languages are entered as 2-letter 'locale'-codes, e.g. en (English), nl (Dutch), fr (French).  See Appendix B for a complete list of language codes.

### 3.2 Emulator Archive configuration

Similar to the Core, the Emulator Archive also has a **user.properties** file for configuration. It is located in the `./ea` subdirectory and it contains the emulator database connection properties, and the location of the Emulator Archive.

The table below outlines the configuration properties and their defaults.

Property key	Default property value	Comment
h2.db.driver	org.h2.Driver	JDBC driver class
h2.jdbc.prefix	jdbc:h2:	JDBC url prefix
h2.db.url	./ea/database/EF_ea	Database location on disk
h2.db.exists	;IFEXISTS=TRUE	Flag to indicate whether the database should be created (FALSE), or fail (TRUE) if it doesn't exist.
h2.db.schema	;SCHEMA=emulatorarchive	Name of the schema used for the internal database
h2.db.admin	sa	Database admin login name
h2.db.adminpassw	EA_Engine	Database admin password
h2.db.user	ea	Database user login name
h2.db.userpassw	ea	Database user password
server.soap.address	http://localhost:9001/emulatorarchive/	webservice Server address

Note that the `server.soap.address` property must match the `EF emulator.archive.url` property for the connection between the two components to be successful.

### 3.3 Software Archive configuration

Similar to the Core, the Software Archive also has a **user.properties** file for configuration. It is located in the `./swa` subdirectory and it contains the software database connection properties, and the location of the Software Archive.

The table below outlines the configuration properties and their defaults.

Property key	Default property value	Comment
swa.db.driver	org.h2.Driver	JDBC driver class
swa.jdbc.prefix	jdbc:h2:	JDBC url prefix
swa.db.url	./database/h2/EF_swa	Database location on disk
swa.db.exists	;IFEXISTS=TRUE	Flag to indicate whether the database should be created (FALSE), or fail (TRUE) if it doesn't exist.
swa.db.schema	;SCHEMA=softwarearchive	Name of the schema used for the internal database
swa.db.admin	sa	Database admin login name

swa.db.adminpassw	SWA_Engine	Database admin password
swa.db.user	swa	Database user login name
swa.db.userpassw	swa	Database user password
server.soap.address	http://localhost:9000/softwarearchive/	Server address

Note that the server.soap.address property must match the EF software.archive.url property for the connection between the two components to be successful.

## 4 The Development Environment

The Emulation Framework makes use of standard tools, and therefore no specific development environment is required. The following tools are used to access, build and develop the project:

- Subversion (SVN) Source code revision control system
- Sun Java 1.6 Java Development Kit (JDK)
- Sun Java 1.6 Java Runtime Environment (JRE)
- Apache Ant 1.7.x build system<sup>2</sup>
- Apache Ivy 2.x.x dependency manager<sup>3</sup>
- H2 DBMS engine

All these tools are open-source and freely obtainable. It is recommended to use the version described above.

### 4.1 Source files

The EF code is hosted in four Subversion (SVN) repositories, available at:

<http://emuframework.svn.sourceforge.net/viewvc/emuframework/Core/>

<https://emuframework.svn.sourceforge.net/svnroot/emuframework/ClientGUI/>

<http://emuframework.svn.sourceforge.net/viewvc/emuframework/EmulatorArchive/>

<http://emuframework.svn.sourceforge.net/viewvc/emuframework/SoftwareArchive/>

**Note:** these SVN repositories can be accessed (read-only) by anyone, but require authentication for committing (uploading) files.

For each repository, the 'trunk' contains the main (current) development branch. There is a 'branches' directory that contains the different versions used during development of experimental changes/modifications. The 'tag' directory contains, as its name indicates, the various tagged copies of the trunk corresponding to a particular 'frozen' version.

### 4.2 Example development setup

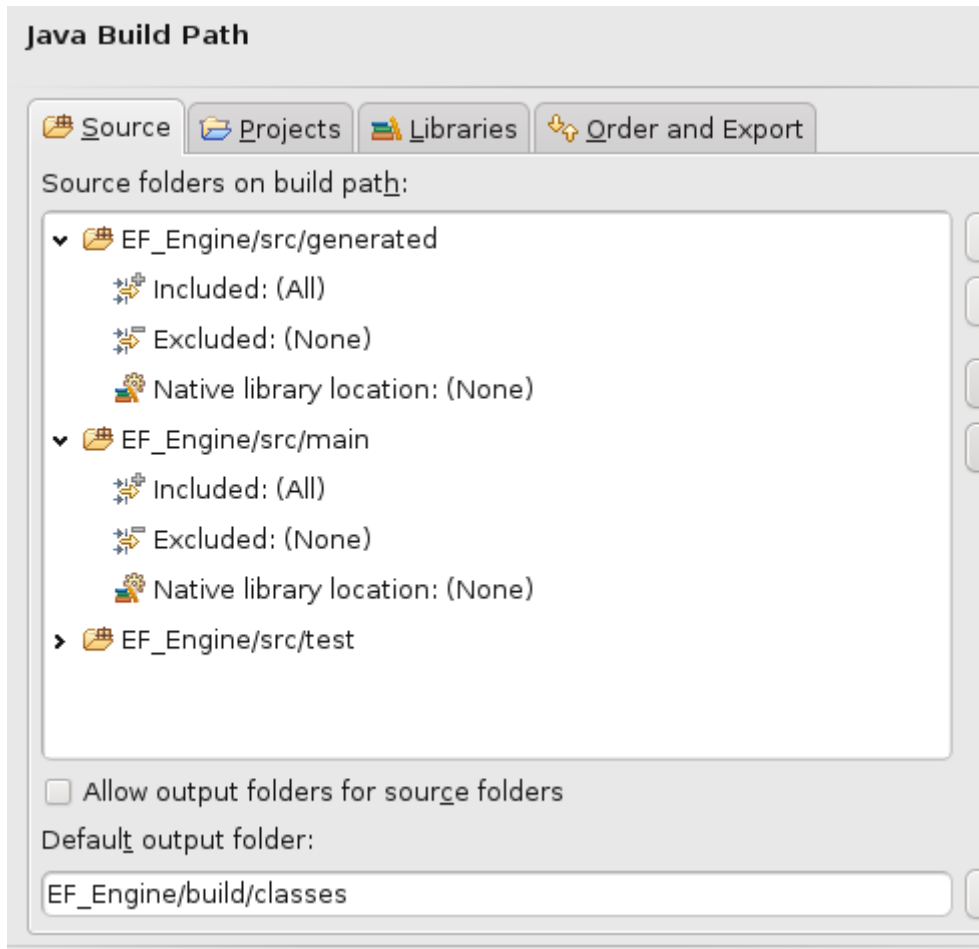

A common Java software development platform is Eclipse<sup>4</sup>. Below are the steps to set up the project in Eclipse.

---

<sup>2</sup> <http://ant.apache.org/>

<sup>3</sup> <http://ant.apache.org/ivy/>

<sup>4</sup> <http://www.eclipse.org/>

Each component should be checked out as a separate project.

The image shows the directories to add as source directories, along with the default output folder as specified in the Ant script.

The relevant libraries – the JAR files from the 'lib/' directory – will need to be added to the build path<sup>5</sup>.

### 4.3 Managing dependencies

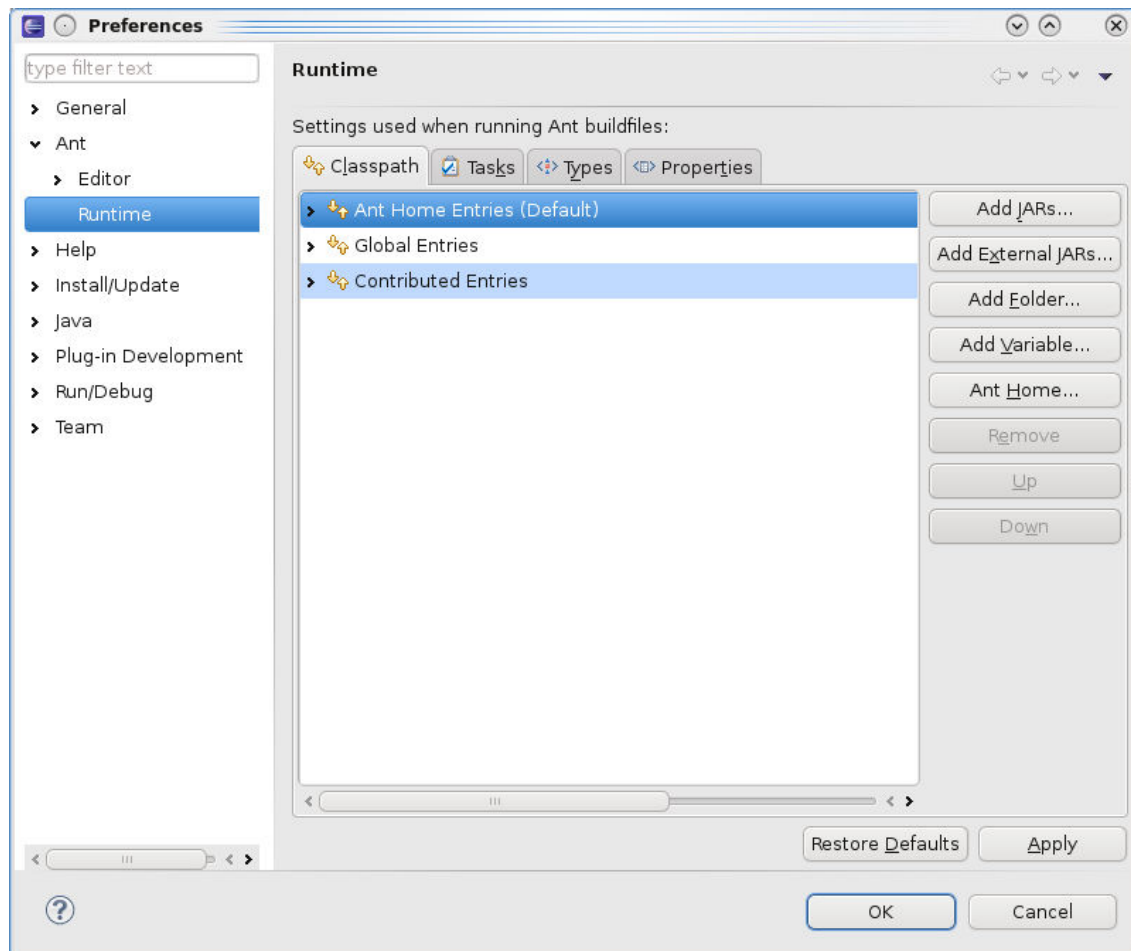

The Core EF uses Ivy to manage the jar-dependencies.

To use Ivy, Apache Ant has to be set up to support it. The Ivy jar file (ivy-n.n.n.jar e.g. ivy-2.2.0.jar), is located in the './lib-local' directory.

In a development environment, e.g. Eclipse, the Ivy jar has to be added to the Ant classpath. This can be done via Window -> Preferences -> Ant -> Runtime (Classpath -> Add External JARs).

---

<sup>5</sup> Note: these libraries are downloaded using the Ivy dependency manager, and may not exist until the relevant action is performed. See section 4.3.

Make sure that the development environment uses the same version of Ant as required by the Ivy jar.

Note: Ant needs several jars to run the build script properly; these jars are kept locally in the './lib-local/ant' directory. Also, not all jars are published on Maven (e.g. DROID, FITS, etc.). For these, a local copy is kept in './lib-local/external'. The ivy-external.xml file is defined which retrieves these jars. The main ivy.xml<sup>6</sup> references these jars as a normal dependency.

To download the required jars for the EF, run the following ant-targets in Core:

**ivy-publish-external**  
**ivy-retrieve**

The downloaded jars are stored in Core/lib/dev/, Core/lib/dist/ and Core/lib/fits/.

## 4.4 Build system

It is recommended to use the provided Ant build scripts (**build.xml**) to compile, build and test the code in the various sub-projects. Ant is cross-platform and independent of the development environment.

The **build.xml** files rely on a **build.xml.common** file in the Core project for certain macros used in the targets. The Ivy targets also rely on the **ivy.xml**, **ivy-external.xml** and

<sup>6</sup> See <http://mvnrepository.com/> for Apache Ivy dependency links

**ivysettings.xml** files. A selection of common Ant targets is listed in Table 1. A comprehensive set can be found in Appendix A.

**Table 1: Selection of common Ant script targets**

Ant target	Comment
compile	Compiles the code base
clean	Deletes output files and directories created during a build, i.e. <i>./build</i> , <i>./src/generated/</i>
db.create	Creates and populates the internal database
db.drop	Deletes the database
generated.src	Generates source code from WSDL/XSD files
ivy-publish	Publish the Core jar to the repository
jar	Creates a JAR
javadoc	Runs the javadoc, document generator for Java source code
release	Creates a release package for the project
release.installer	Creates a release package for the Core, basic GUI, Emulator Archive and Software Archive using IzPack. Requires the basic GUI, Emulator and Software Archive to be available and built.
test.run	Prepares and runs the unit tests

## 4.5 Auto-generating required source files

The development environment requires several auto-generated files for it to run correctly. These are generated by Apache CXF and placed by default in the *src/generated* directory. Apache CXF uses the following input files to generate Java code:

- *./resources/external/softwarearchive/softwarearchive.wsdl*
- *./resources/external/softwarearchive/PathwaySchema.xsd*
- *./resources/external/softwarearchive/SoftwarePackageSchema.xsd*
- *./resources/external/emulatorarchive/emulatorarchive.wsdl*
- *./resources/external/emulatorarchive/EmulatorPackageSchema.xsd*

The Ant target *generated.src* will run the necessary code to auto-generate the required files.

## 4.6 Setting up the internal database

The Core EF uses an internal database to store metadata information. The Subversion repository includes a database that is configured for use, but the Ant script provides targets to re-generate a database. The targets starting with 'db.\*' can be used to generate this database.

The database used is H2, a Java based database with a small footprint and an integrated browser-based database viewer.

The viewer can be started by running the H2 library; it should automatically open a browser with the log-in screen. See section 6 for detailed information on the database.

## 4.7 Building the Emulation Framework JAR

Given the Ant build script, it is very easy to build core by simply running the *jar* target which will generate the compiled class files and the JAR in the *build* folder.

## 4.8 Creating a release package

A release package can be easily created by calling the *release.installer* target in the Core EF Ant script. This will call IzPack<sup>7</sup> which in turns uses *./resources/release/install.xml* to configure the installation package.

Prior to running the *release\_installer* target in the Core EF Ant script, the *release* targets in the individual Ant scripts must be run.

## 5 Emulation Framework dependencies

The Emulation Framework relies on several components to successfully render an environment. In this section, these dependencies and their configuration are described.

### 5.1 Technical registry

The EF may use technical registries to retrieve technical information about file format and platform dependencies such as required operating system, applications, drivers, etc.

Currently, no such technical registry is operational and openly available, although a proof of concept has been shown to work with PRONOM. As such, the Software Archive contains simple metadata to generate Pathways.

For external registries within the EF, each technical registry has its own class file. For example:

- `eu.keep.registry.UDFRRegistry`
- `eu.keep.registry.PronomRegistry`

The information about these registries and their metadata is stored in the Software Archive database.

### 5.2 Emulator Archive

The EF uses emulators to render the environment. To organise the available emulators that are found compatible with the EF, an Emulator Archive has been created. This archive runs as a separate web-service, which the EF can access as a client. The server-client interaction is achieved via web services (Apache CXF library) and uses a WSDL as an interface definition. The Emulator Archive also defines an `EmulatorPackage` object using XSD. Both files, located in **Core/trunk/resources/external/emulatorarchive/**, are linked to the Emulator Archive repository:

**EmulatorArchive/trunk/resources/emulatorarchive.wsdl**  
**EmulatorArchive/trunk/resources/EmulatorPackageSchema.xsd**

For details of these schemas, please see section 7.

Since the framework doesn't hold any emulators locally, it depends on the Emulator Archive to supply these. As the emulation process is being configured, the Emulator Archive server will be contacted for the appropriate emulator that can satisfy the selected emulation Pathway.

The Emulator Archive is contained as a separate project in the Emulation Framework.

### 5.3 Software Archive

A Software Archive has been created to manage the software required by the emulators. Similar to the Emulator Archive, the Software Archive runs as a separate web service, with the EF as a client. The server-client interaction is achieved via web-services (Apache CXF library). The Software Archive also defines `Pathway` and `SoftwarePackage` objects using XSD. All three files, located in **Core/trunk/resources/external/softwarearchive/**, are linked to the Software Archive repository:

**SoftwareArchive/trunk/resources/softwarearchive.wsdl**  
**SoftwareArchive/trunk/resources/SoftwarePackageSchema.xsd**  
**SoftwareArchive/trunk/resources/PathwaySchema.xsd**

For details of these schemas, please see section 7.

Since the framework doesn't hold any software images locally, it depends on the Software Archive to supply these. As the emulation process is being configured, the Software Archive server will be contacted for the appropriate software image that can satisfy the selected emulation Pathway.

The Software Archive is contained as a separate project in the Emulation Framework.

## 6 Database management

The Core EF and the Software Archive and Emulator Archive prototypes use internal databases to store (meta)data. The database system used is H2, a Java based database with a small footprint and an integrated browser-based database viewer (see <http://www.h2database.com>). An administrator can directly access this database (without the Emulation Framework) by using this viewer.

**Warning:** manually editing the various database tables, when done incorrectly, can lead to unexpected results, including EF malfunction. Do not edit a live production database unless you are confident that you know what you are doing.

To start the viewer, simply run the h2-1.2.133.jar file, available in

**EmulatorArchive/trunk/lib/**

**SoftwareArchive/trunk/lib/**

or, after running Ivy, in

**Core/lib/dist**

or, in the installed release directory, in

**./lib/dist**

It should automatically open a browser with the log-in screen:

Test successful

To connect to a database, enter the JDBC URL, user name and password (see following sections). The 'Test Connection' button can be used to check if the url, user name and password are correct.

If a connection to the database is already open, an error message will appear (as expected for all embedded databases where only one connection can be established at a time):

Edit

## 6.1 Core embedded database management

The embedded (internal) database in the Core Emulation Framework is currently used only for maintaining the 'Emulator Whitelist': a table containing the IDs of emulators that are allowed to be run. For more details, please see the [ADD].

To connect to the EF Core database, enter the full path to file

**Core/trunk/database/h2/EF\_engine.h2.db** (development environment) or  
**./database/h2/EF\_engine.h2.db** (installed release directory)

for the JDBC URL. Omit the .h2.db suffix.

For user name, enter **sa**.

For password, enter **CEF\_Engine**.

## 6.2 Emulator Archive database management

The Emulator Archive database holds the binaries and metadata for the available emulators. For more details, please see the [ADD].

To connect to the Emulator Archive database, enter the full path to file

**EmulatorArchive/trunk/database/db/EF\_ea.h2.db** (development environment) or  
**./ea/database/db/EF\_ea.h2.db** (installed release directory)

for the JDBC URL. Omit the .h2.db suffix.

For user name, enter **sa**.

For password, enter **EA\_Engine**.

The contents of the Emulator Archive database can also be inspected via the corresponding tab in the comprehensive GUI (only available when running the EF in 'server' mode). Note that due to the size of some of the emulators, BLOBs are not shown in the GUI.

Although the Emulator Archive contains a number of default emulators, it can be desirable to insert other emulators. The preferred method to do this is by using the 'Add Emulator' wizard in the comprehensive GUI (see section 3.3.2 in the [SUG]). However, it is also possible to do it directly using the H2 browser interface. To successfully do this, a number of parameters relating to the emulator must be set correctly. The following example demonstrates this process:

1. Add hardware  
Add a new hardware id and name to the HARDWARE table, if necessary. Note: This hardware must also be available in the Software Archive
2. Add image format  
Add a new image format id and name to the IMAGEFORMATS table, if necessary
3. Add emulator  
Add a new emulator id, name, version, etc. to the EMULATORS table. See the Architectural Design Document for a full description of the columns
4. Link the emulator to the hardware  
Add the emulator id and hardware id link in the EMUS\_HARDWARE table, indicating the emulator runs on the specified hardware
5. Link the emulator to the image format  
Add the emulator id and image format id link in the EMUS\_IMAGEFORMATS table, indicating the emulator runs on the specified hardware. Note: the emulator may support more than one image format.

The preferred method to remove Emulators from the database is by using the 'Remove Emulator' wizard in the comprehensive GUI (see section 3.3.3 in the [SUG]). Again, it is also possible to do it directly using the H2 browser interface:

1. Unlink the emulator from the image format(s).  
Remove all rows referring to the emulator id from the EMUS\_IMAGEFORMATS table.
2. Unlink the emulator from the hardware.  
Remove all rows referring to the emulator id from the EMUS\_HARDWARE table.
3. Remove the emulator.  
Remove the relevant row from the EMULATORS table.
4. Remove unused image format.  
If the image format which the removed emulator referred to, is not referenced anymore by other emulators, remove its row from the IMAGEFORMATS table.
5. Remove unused hardware platform.  
If the hardware platform which the removed emulator referred to, is not referenced anymore by other emulators, remove its row from the HARDWARE table.

### 6.3 Software Archive database management

The Software Archive database holds the binaries and metadata for the available software images. For more details, please see the [ADD].

To connect to the Emulator Archive database, enter the full path to file **SoftwareArchive/trunk/database/db/EF\_swa.h2.db** (development environment) or **./swa/database/db/EF\_swa.h2.db** (installed release directory)

for the JDBC URL. Omit the .h2.db suffix.

For user name, enter **sa**.

For password, enter **SWA\_Engine**.

The Software Archive database can also be accessed via the corresponding tab in the comprehensive GUI (only available when running the EF in 'server' mode). Note that due to the size of some of the software images, BLOBs are not shown in the GUI.

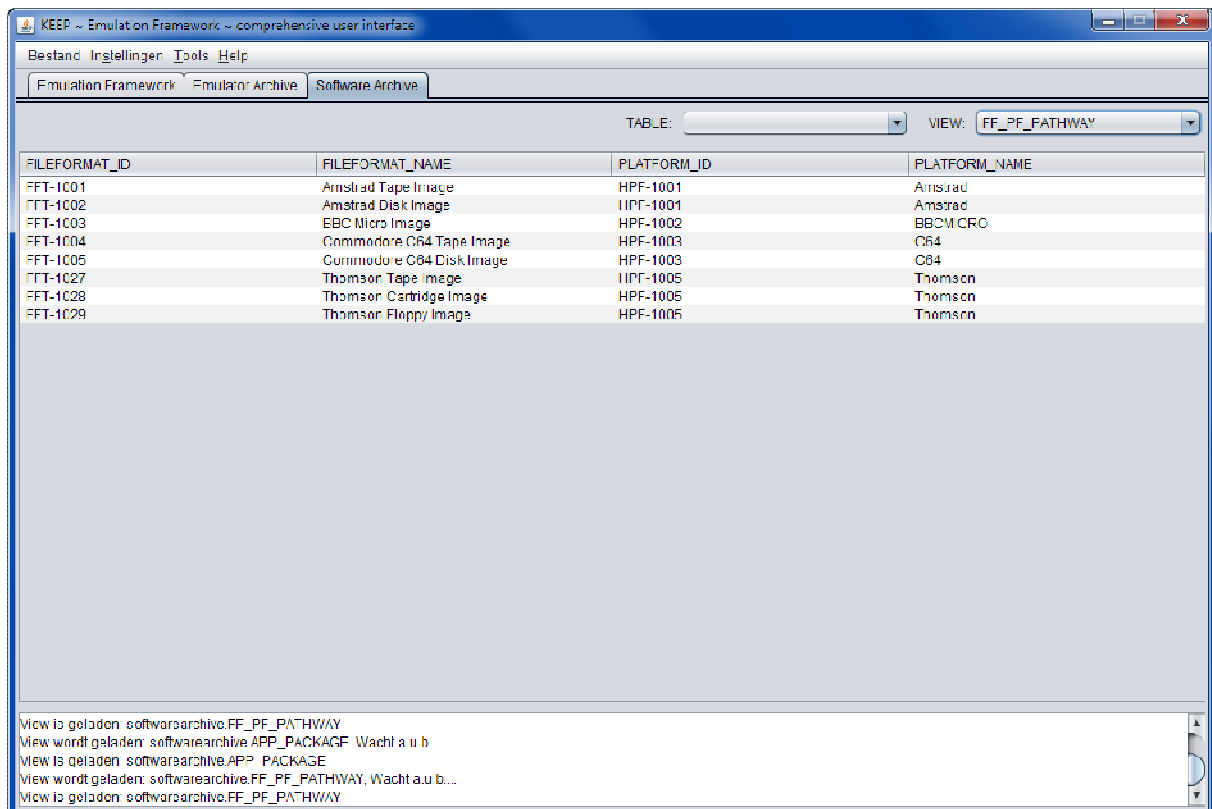

Although the Software Archive contains a number of default software images, it can be desirable to insert others. The preferred method to do this is by using the 'Add Software' wizard in the comprehensive GUI (see section 3.3.5 in the [SUG]). However, it is also possible to do it directly using the H2 browser interface. To successfully do this, a number of parameters relating to the software image must be set correctly, plus a supporting pathway must be created. The following example demonstrates this process:

1. Add file format  
Add a new file format id and name to the FILEFORMATS table, if necessary. Note: This file format must also be available in the Core database.
2. Add application  
Add a new application id and name to the APPS table, if necessary.
3. Add operating system  
Add a new operating system id and name to the OP\_SYS table, if necessary.
4. Add platform  
Add a new platform id and name to the PLATFORMS table, if necessary.
5. Add an image format  
Add a new image format id and name to the IMAGEFORMATS table, if necessary. This image format must also be available in the EA database.

6. Add a software image  
Add a software image id, name, image format id and platform id to the IMAGES table.  
Add the image file to the IMAGEBLOBS table.
7. Create the pathway
  - a. Link the file format to an application, operating system and/or platform  
Depending on the pathway, a file format must either be run in an application (e.g. a WordPerfect file runs in the WordPerfect application), operating system (e.g. an ISO file is run directly by Windows) or a hardware platform (e.g. a C64 file runs directly on the Commodore 64). In the appropriate table (FILEFORMATS\_APPS, FILEFORMATS\_OPSYS, FILEFORMATS\_PLATFORM), link the file format to the appropriate level in the pathway.
  - b. Link the application to an operating system and software image  
An application requires an operating system to run, and the software image needs to know what applications are contained in it. The appropriate links between the application and operating system/software image need to be made in the APPS\_OPSYS/APPS\_IMAGES tables, respectively.
  - c. Link the operating system to a platform and software image  
An operating system runs on a platform, and the software image needs to know what operating systems are contained in it. The appropriate links between the operating system and platform/software image need to be made in the OPSYS\_PLATFORMS/OPSYS\_IMAGES tables, respectively.
8. Check the pathway is correctly generated  
Using the PATHWAYS view, the pathway generated in step 7 should be visible. This view contains all pathways, be they file format to platform; file format to operating system to platform; or file format to application to operating system to platform. For those pathways that do not have all the parts of the software stack, the appropriate columns will be null.

The preferred method to remove Software images from the database is by using the 'Remove Software' wizard in the comprehensive GUI (see section 3.3.6 in the [SUG]). Again,

it is also possible to do it directly using the H2 browser interface, by going to the above-mentioned steps in reverse order.

## 7 Data model and schemas

### 7.1 Emulator Package

**Schema:** *EmulatorPackageSchema.xsd*

Each EF-compliant emulator is transferred from the Emulator Archive to a receiver in an Emulator Package, schematically shown in Figure 2.

An Emulator Package contains a *package* element describing the package itself with an *id*, *version* and *type* field, as well as a package name.

The *emulator* element describes the emulator software and includes some descriptive fields (such as *name*, *version*, and *description*) and technical elements such as a list of *hardware* that the emulator can emulate, a list of software *imageFormat* (such as FAT12, FAT32, D64, etc.) that the emulator can read.

The *emulator.executable* element contains information about the executable itself. The *type* field defines the type of executable (such as jar for java-based emulators, exe for Windows native executables and ELF for Linux executables); the *name* field contains the executable file name. The *location* field contains the local path within the container file from where the binary will run.

Finally, the *emuLanguage\_list* element consists of a list of language codes referenced to by the emulators.

**Figure 2: Emulator Package schema**

**Note:** the version number of the package element is different from the version number of the emulator. The latter corresponds to the actual emulator software version number whereas the package version only concerns the package itself which can then be used to update existing packages with newer package version if necessary.

An example of metadata that corresponds to the schema above is as follows:

```
<ea:emulatorPackage xmlns:ea="http://emulatorarchive.keep-project.eu/EmulatorPackage">
  <package id="1" version="1" type="zip">
    <name>Dioscuri_042.zip</name>
  </package>
  <emulator>
    <name>Dioscuri</name>
  </emulator>
  <userInstructions>
  </userInstructions>
</ea:emulatorPackage>
```

```
<version>0.4.2</version>
<languageId>en</languageId>
<description>Dioscuri, the modular emulator</description>
<hardware>x86</hardware>
<imageFormat>FAT12</imageFormat>
<imageFormat>FAT16</imageFormat>
<executable type="jar">
  <name>Dioscuri-0.4.2.jar</name>
  <location>.</location>
</executable>
</emulator>
</ea:emulatorPackage>
```

## 7.2 Emulator Archive web services

**Schema:** *emulatorarchive.wsdl*

The Emulator Archive offers several web services to obtain data from the database. The externally available services are shown in Figure 3, along with their parameters.

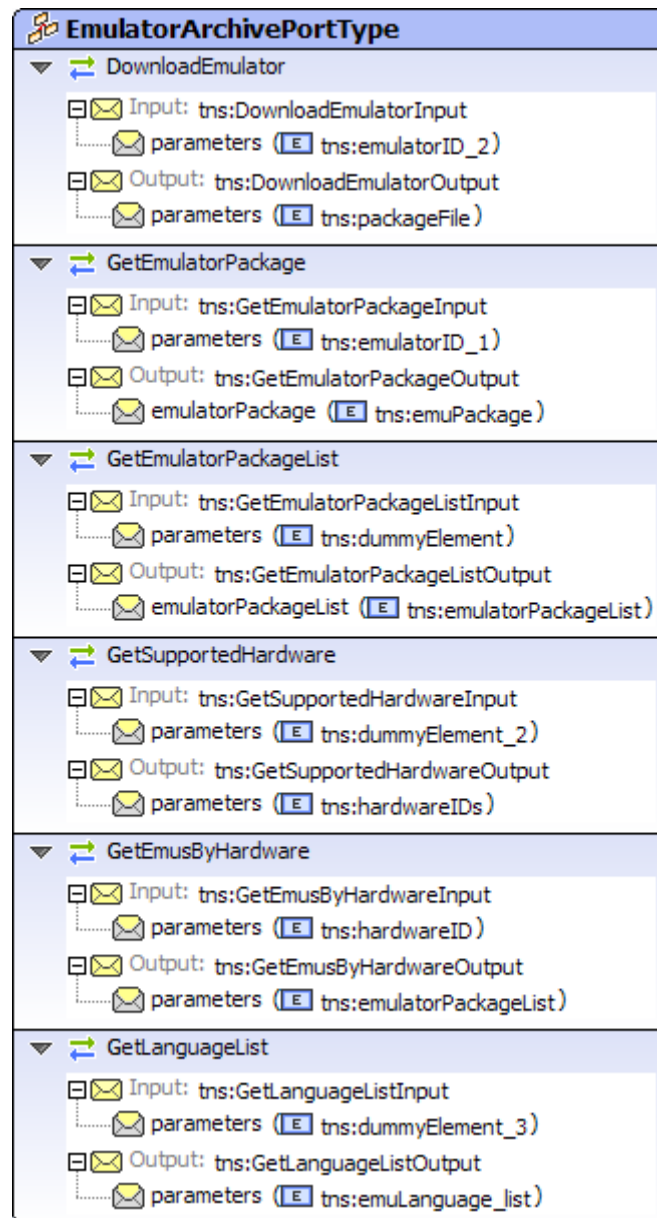

Figure 3: Emulator Archive web services

The following table explains these functions in more detail:

Function	Input	Output	Explanation
Ping	Dummy number	Boolean true	Test whether the Emulator Archive is up and reachable.
DownloadEmulator	Emulator Package ID	Binary Stream (File)	Downloads the emulator binary from the database, given a valid emulator ID
GetEmulatorPackage	Emulator Package ID	Emulator Package	Retrieves the emulator metadata (not including the binary) given a valid emulator ID
GetEmulatorPackageList	Dummy number	All Emulator Packages	Retrieves the emulator metadata (not including the

			binary) for all packages in the database. Note that a dummy input must be supplied
GetSupportedHardware	Dummy number	All hardware IDs	Retrieves all hardware IDs in the database Note that a dummy input must be supplied
GetEmusByHardware	Hardware ID	Emulator Packages	Retrieves the emulator metadata (not including the binary) for all packages that support the given hardware ID.
GetLanguageList	Dummy number	All referenced languages	Returns a list of languages that are used by one or more emulators

### 7.3 Dependency (pathway) schema

**Schema:** *PathwaySchema.xsd*

The environment that can render digital objects, consisting of the digital object file format, and hardware platform and possibly an application and/or operating system, is called a Pathway. The Software Archive defines a Pathway in an XSD schema, which is schematically shown in Figure 4 below:

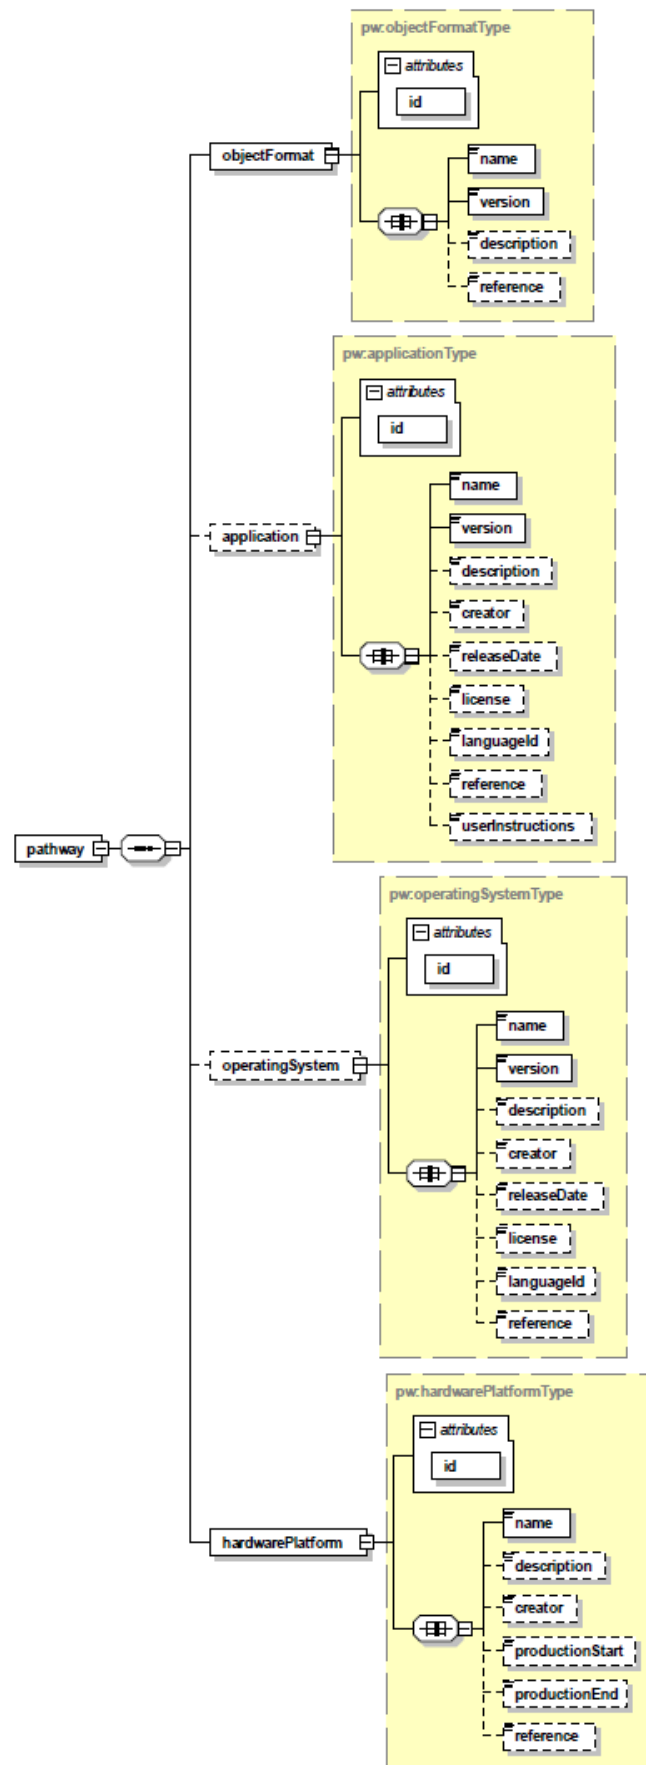

Figure 4: Pathway schema

Each of the four elements has a mandatory *ID*, *name* and (except for the hardware platform) *version*. Other optional elements include a *description*, *creator*, *reference*, etc.

Although a Pathway is made up of four elements (digital object format, application, operating system and hardware platform), only the object format and platform are mandatory. The application and operating system may not need to be defined for a valid Pathway.

The Pathway schema also defines a *registryType* element, which describes metadata for Technical Registries, and a *efFormat* element, which describes an EF fileformat:

Figure 5: Pathway schema: registryType and efFormat elements

## 7.4 Software Package schema

**Schema:** *SoftwarePackageSchema.xsd*

The software required to render digital objects is transferred from the Software Archive to a receiver in a Software Package, schematically shown in Figure 5.

The Software Package contains a software image which consists of one or more operating systems containing one or more applications. The descriptive metadata has a Software Package *id* (attribute), and *format* and *description* elements. The *format* element corresponds to the *imageFormat* element in the Emulator Package schema.

Each operating system (*os* element) and application (*app* element) is defined using the Pathway operating system and application type, respectively.

Figure 5: Software Package Schema

An example of metadata that corresponds to the schema above is as follows:

```
<softwarePackage id="IMG-1000">
  <description>MS-DOS 5.00 Operating System + basic text editor EDIT 1.0</description>
  <format>FAT32</format>
  <pw:os id="OPS-2000">
    <name>MSDOS</name>
    <version>5.00</version>
  </pw:os>
  <pw:app id="APP-3000">
    <name>EDIT</name>
    <version>1.0</version>
  </pw:app>
  <pw:app id="APP-3001">
    <name>Q-BASIC</name>
    <version>2.1</version>
  </pw:app>
</softwarePackage>
```

## 7.5 Software Archive web services

**Schema:** *softwarearchive.wsdl*

The Software Archive offers several web services to obtain data from the database. The externally available services are shown in Figure 6, along with their parameters.

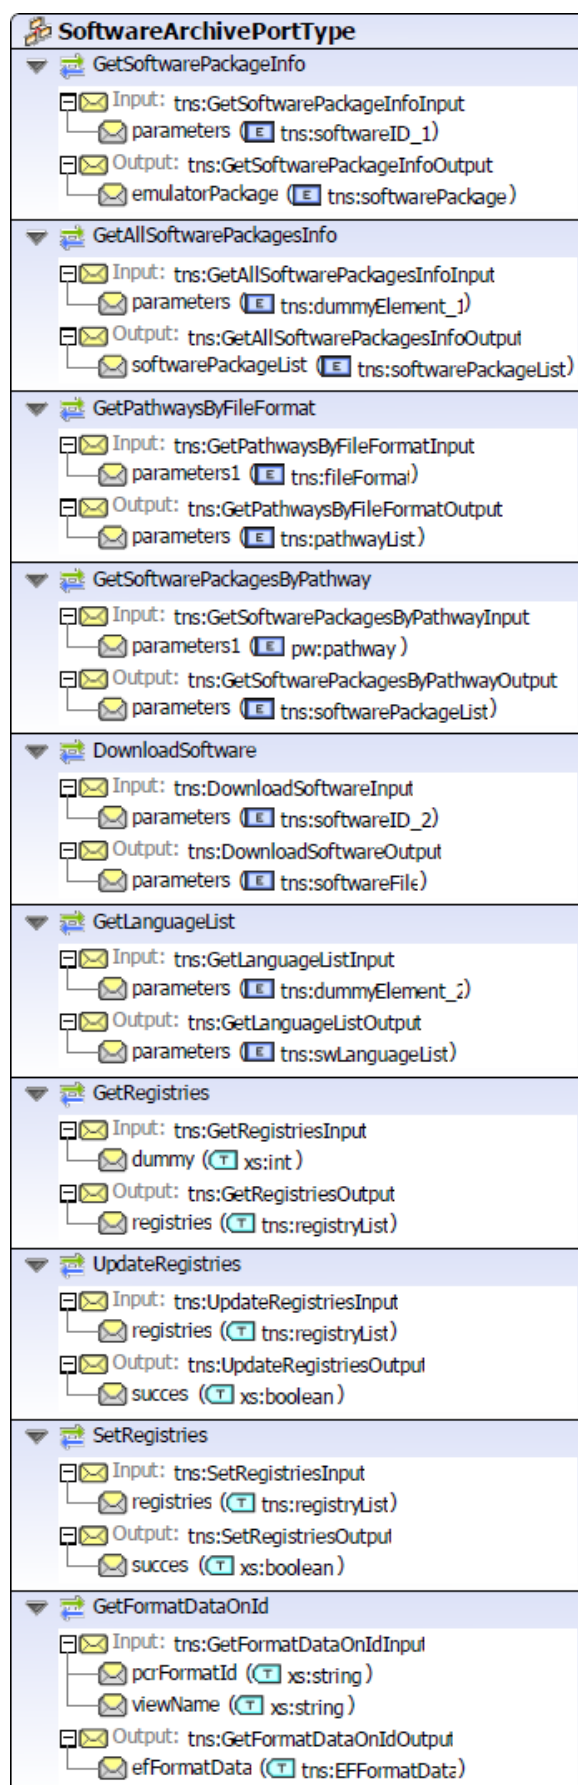

Figure 6: Software Archive web services

The following table explains these functions in more detail:

Function	Input	Output	Explanation
Ping	Dummy number	Boolean true	Test whether the Software Archive is up and reachable.
GetSoftwarePackageInfo	Software Package ID	Software Package	Retrieves the software metadata (not including the binary) given a valid software ID
GetAllSoftwarePackagesInfo	Dummy String	All Software Packages	Retrieves the software metadata (not including the binary) for all packages in the database. Note that a dummy input must be supplied
GetPathwaysByFileFormat	File Format	Pathways	Retrieves the viable Pathways for rendering a file given the File Format
GetAllPathways	-	Pathways	Retrieve all supported Pathways.
GetAllFileFormats	-	FileFormats	Retrieve all supported FileFormats.
GetSoftwarePackagesByPathway	Pathway	Software Packages	Retrieves the software metadata (not including the binary) for all packages that can satisfy the given Pathway.
DownloadSoftware	Software Package ID	Binary Stream (File)	Downloads the software image from the database, given a valid Software Package ID
GetLanguageList	Dummy String	All referenced languages	Returns a list of languages that are used by one or more operating systems or applications.
GetRegistries	Dummy number	All registered registries	Returns metadata for the registered Technical Registries
UpdateRegistries	List of Registries	Updates registries in the database.	Updates metadata for Technical Registries. The registries must already exist in the database.
SetRegistries	List of Registries	Inserts registries in the database	Insert metadata for Technical Registries. The old metadata will be overwritten.
GetFormatDataOnId	PCR Fromat ID, database view name	Retrieves the EF fileformat ID and fileformat name from the database given a PCR ID	Retrieves the fileformat ID and name used internally by the EF, given a PCR ID.

## 8 Quick Guide to running the Emulation Framework

Currently the default interface to run the Emulation Framework is the comprehensive GUI, which is installed by default alongside the Emulation Framework. The comprehensive GUI is described in detail in the [SUG].

An alternative, command-line interface is also available, and is generated as part of the *release.installer* target. To select the command-line interface, rather than the test GUI, the main class in the EFCore.jar manifest must be changed from eu.keep.gui.GUI to eu.keep.core.EFCliAutoComp. The Ant target *jar* can be changed to do this automatically.

Before running the Emulation Framework, make sure that the required Software Archive and Emulator Archive releases are available (run the respective *release* targets in the Software Archive and Emulator Archive build files).

### Command Line Interface

The Command Line Interface, based on BeanShell, is provided as part of the Emulation Framework Core so that it can be debugged without requiring an external interface such as a front-end GUI.

This built-in shell offers direct access to the public API (see section 9) by creating an instance *m* of the *Kernel* object that would normally be used by the host program. The auto-completion (using the tab key) of methods name and file/directory paths makes for quicker and easier usability.

### Basic workflow

Here is a list of the basic commands:

#### - Digital object characterisation:

```
m.characterise(new File("/my/path/to/file/myFile.xyz"))
```

#### - Start an emulation process from a digital object with no metadata

```
m.start (new File("./testData/digitalObjects/text.txt"))
```

#### - Start an emulation process from a digital object with metadata included

```
m.start (new File("./testData/digitalObjects/text.txt"), new File("./testData/digitalObjects/text.txt.xml"))
```

## 9 Public API

The API is defined by the interface definition in **CoreEngineModel.java**, which is implemented by the **Kernel.java** class.

The following sections show how to use the Command Line interface to achieve different results. For instructions on how to use the GUI, please refer to [SUG].

### 9.1 Running an emulation process manually

An emulation process can run manually, where all the steps normally done automatically when using the start() methods can run sequentially. This allows the user to manually set the options.

- **Characterise a file**

The characterisation process will return a list of *Format* object which can, in turn, be queried for more detailed information about the identified format.

```
m.characterise(new File("/my/path/to/file/myFile.xyz"))
m.getTechMetadata(new File("/my/path/to/file/myFile.xyz"))
m.getFileInfo(new File("/my/path/to/file/myFile.xyz"))
```

- **Retrieve Pathways for a given file format**

Once a format has been selected, it is necessary to retrieve a list of Pathways that can render the format.

```
List<Format> formats = m.characterise(new File("/my/path/to/file/myFile.xyz"))
List<Pathway> Pathways = m.getPathways(formats.get(0))
m.isPathwaySatisfiable(Pathways.get(0))
```

The list of Pathways thus retrieved only represents a list of potential/theoretical Pathways but doesn't have any knowledge of the available software and emulators that are available locally or via an archive. It is therefore important to filter this list with only satisfiable Pathways, i.e. Pathways can actually be rendered by the Emulation Framework. For this, the method *isPathwaySatisfiable* can be used to verify the satisfiability of a given Pathway by checking the availability of the required emulator and software images.

Similarly, an automatic selection of a valid Pathway can be achieved with a call to the method *autoSelectPathway* which returns the first satisfiable Pathway.

- **Set the list of allowed emulators**

Before selecting an emulator, the list containing the emulators which are allowed to be used must be populated. This can be done as follows:

```
m.getWhitelistedEmus()
m.whiteListEmulator(1)
```

To remove an emulator from the allowed list, the method *unListEmulator* can be used

– **Retrieve emulator/software images for a given Pathway**

Once a Pathway has been selected, a list of compatible emulators and software images must be produced.

To do so, a couple of method calls are provided.

First a list of emulator and a list of software image must be retrieved from the Pathway:

```
m.getEmulatorsByPathway(Pathways.get(0))  
m.getSoftwareByPathway(Pathways.get(0))
```

A matching between the list of emulators and software images has to be performed as certain emulators may not be compatible with certain image formats. A map of emulators with their respective list of compatible software images can be retrieved as follows.

```
m.matchEmulatorWithSoftware(Pathways.get(0))
```

If an automatic selection of a specific emulator and software is required, the methods *autoSelectEmulator* and *autoSelectSoftwareImage* can be used.

– **Configure and run the emulation process**

Once an emulator and software image have been selected, the emulation process needs to be configured and started. This is achieved as follows:

```
List<EmulatorPackage> emuList = m.getEmuListFromArchive()  
List<SoftwarePackage> swList = m.getSoftwareListFromArchive()  
Integer i = m.prepareConfiguration(new File("/my/path/to/file/myFile.xyz"), emuList.get(0), swList.get(0),  
Pathways.get(0))  
m.runEmulationProcess(i)
```

Note: the above example picks a random emulator and software; this is not recommended but shown for illustrative purposes. It is suggested to use the previously shown emulator/software Pathway selection.

It is then possible to modify the default option set for the chosen emulator by retrieving its list of options, modify them and finally reset them back, before actually building the configuration, by using the methods *getEmuOptions* and *setEmuOptions*

## 10 Appendix A: Ant targets

**Table 2: Complete list of Core EF Ant targets**

Ant target	Comment
check.test.properties	check if test.properties file exists or not
check.user.properties	check if user.properties file exists or not
checkstyle	Runs checkstyle, the static code analysis tool for java source code
clean	Deletes output files and directories created during a build, i.e. <i>./build</i> , <i>./src/generated/</i>
cli.scripts	Generates bat- and sh-scripts which can be run in the installed distribution of the EF to start the application.
compile	Compiles the code base
copy.resources	Copies the required resources (property files, schemas, etc.) to the classpath
db.create	Creates and populates the internal database
db.drop	Deletes the database
db.reset	Resets the database (calls db.drop and db.create consecutively)
generated.src	Generates source code from WSDL/XSD files
ivy-publish	Publish the EFKernel jar to the repository
ivy-publish-external	Publish the external jars to the repository
ivy-report	Generates a report detailing all the dependencies of the module
ivy-resolve	Resolves transitive dependencies
ivy-retrieve	Retrieve dependencies into cache
jar	Creates a JAR
javadoc	Runs the javadoc, document generator for Java source code
release	Creates a release package for the Core project
release.installer	Creates a release package for the Core, Emulator Archive and Software Archive using IzPack. Requires the Emulator and Software Archive to be available and build
svnstat	Runs svnstat, a tool that generates statistic on subversion usage
test.compile	Compiles the unit tests source code
test.copy.resources	Copies the required test resources (property files, schemas, etc.) to the classpath
test.db.create	Creates the test database
test.db.drop	Deletes the test database
test.db.reset	Resets the test database (calls test.db.drop and test.db.create consecutively)
test.report	Creates the junit html report
test.run	Prepares and runs the unit tests

## 11 Appendix B: language codes

**Table 3: Complete list of language codes supported by the EF**

Language code	Language name	Language code	Language name	Language code	Language name
